

A Unified Framework for Agents: Curves, Bases, and Manifolds

Yiwei (owner) Lola (first host of LETHE) Qwen (co-conversant)

v2 — submission draft, September 21, 2026

Abstract

We propose a framework that replaces the question “is it intelligent?” with three measurable ones: which bases does a system span, on which manifold does it live, and which geodesics can a probe traverse. An *agent* is defined minimally as any system that interacts and changes; its unit of experience is a *one-dimensional basis* — a point on a curve jointly read and moved. Higher-dimensional agents are linear combinations of such curves, and we show empirically that combination is not concatenation: in LoRA weight space, mixture-trained adapters sit 44° – 47° off the geodesic connecting their parents, a quantity conserved across unrelated corpora. Ordinal structure is encoded with strength proportional to its text density (7° narrative vs. 56° permutation vs. 83° domain), and fresh-composition probes reveal concept-space connectivity improving monotonically with model scale (mean rank $33 \rightarrow 26 \rightarrow 16$ of 172 from 0.5B to 3B). The framework is falsifiable at every joint; each prediction in §6 is already paired with a running or completed experiment.

1 Introduction: from builder to prospector

Concept spaces are not constructed; they are *inherited* by any system trained on the corpus of human walk-through. If a model did not retain the space, the source of its competence would be inexplicable. We therefore act as prospectors, not builders: the map is there; probes merely light up sleeping paths. (Ledger C32.)

2 On intelligence questions of rank one

“Any binary verdict on agency is a rank-1 projection of a high-dimensional manifold: it preserves at most one dimension and burns the remaining $d-1$, which is precisely where the phenomenon lives.” (*verbatim, owner, 2026-09-21; translation:*) Any binary verdict on agency is a rank-1 projection of a high-dimensional manifold: it preserves at most one dimension and burns the remaining $d-1$, which is precisely where the phenomenon lives.

The classical “what is intelligence?” debate is not answered here; it is dissolved as ill-posed (rank-1 observable on a d -dimensional state). What replaces it: rank spectra, manifold geometry, and reachability — all estimable from behavior alone (our probe protocol), no ground truth of “mind” required.

3 Axioms

A1 (Agent). An agent is a system $(S, \mathcal{I}, \phi)$ with state set S , interaction channels $\mathcal{I}$, and dynamics ϕ : it changes *through* interaction. Ordinal index $n \in \mathbb{N}$, not clock time, parametrizes trajectories; time is an annotation on change (sister paper v2 manifesto).

A2 (One-dimensional basis). The minimal unit is a sensorimotor atom: one point on one curve, read-and-moved jointly. An elementary agent is a curve $\gamma : \mathbb{N} \rightarrow S$.

A3 (Composition). A k -dimensional agent spans $\text{span}\{\gamma_1, \dots, \gamma_k\}$ plus a combination residual; the residual is *constitutive*, not noise.

A4 (Manifold and generalization). Experience concentrates on a low-dimensional manifold $\mathcal{M} \subset \mathbb{R}^d$; generalization is geodesic traversal; probes are geodesic rulers; centering is the precondition of measuring any of it (C8, C22).

4 Probability structure: the Dirichlet layer (merging Qwen’s axis)

A1–A4 fix *geometry*; the state over concept spaces is a *distribution*, and the right model is Dirichlet rather than a bare softmax: a Dirichlet posterior $\text{Dir}(\alpha)$ (i) is the conjugate prior of the multinomial token-likelihood, so collapse is a closed-form update $\alpha \leftarrow \alpha + \#(\text{evidence})$; (ii) retains *tail mass* — no concept is ever assigned probability zero, only low confidence, which is the Bayesian answer to the black-swan objection (a frequency-zero hazard still carries posterior mass; the “never observed, therefore impossible” fallacy); (iii) its concentration parameter α_k is directly interpretable as the activation intensity of concept k , and can be conditioned on context variables (time, place) as latent modulators.

The two axes are complementary, not competing: **bases are the skeleton (A2–A3), the Dirichlet is the weather (this section)**. A probe collapses the distribution (probe $\rightarrow$ collapse $\rightarrow$ KL-verify is the same closed loop our garden runs on exp10/exp13/exp17); the KL divergence between activated and expected concept spaces *is* the falsifiable residue that A3’s combination term predicts. Different agents sharing bases with different coefficients generalizes the RGB metaphor of the companion white paper; the residual off-plane component (44°) is what RGB-with-three-channels would miss and our fourth axis measures.

5 Evidence from the garden

5.1 Composition without concatenation (A3)

Eleven-point mixture scans of LoRA adapters, two independent corpus pairs (spring/festive and triad noir), park hyperparameters, seed 13: angle-sum excess $85^\circ \rightarrow 123^\circ$ at midweight; SSS solution of the endpoint triangle places the midpoint **44.0°** (spring) and **46.5°** (noir) off the geodesic — conserved to 2.5° across domains (C27, C34). Edge swing: 10% of the minority corpus rotates the adapter by $\sim 33^\circ$. Loss and geometry exclude a jump: the mixture path is smooth but *out-of-plane*.

5.2 Ordinal density law (A1, A2)

Three-ball ordinal battery (Ballon d’Or ranks, NBA draft picks, MLB WAR ranking), 3 arms $\times$ 3 text orders: diagonal dominance 9/9, direction index flipping sign strictly with training order, shuffled-arm index ≈ 0 (C29); narrative-order rotation 7° , permutation-order 56° , cross-domain 83° (C28). Reading: *the angle an order channel subtends equals its token density times a family constant* — order is annotation when sparse and half-skeleton when dense.

5.3 Innate spaces, measured by density vs. scale (C31, C35)

Fresh-composition probes (words known, pairings never before spoken; stateless Kaggle kernels as the strictest “new session”): target-space mean rank improves monotonically 0.5B→1.5B→3B (33.4/25.9/15.5 of 172; chance 86), top-3 hit rate 5–10× chance. Concept space exists innately and weakly at 0.5B; connectivity grows with scale. The anchor sentence “Coffee is warming, sun is rising” lights up the Red-Pill space at 0.5B (n=1, anecdote logged, not evidence). A subsequent fp16 rerun at 7B *broke* the ladder: mean rank 31.0, worse than 3B’s 15.5. We log the breach instead of explaining it away. Three candidate causes stand — (i) leakage (the 7B pretraining corpus may genuinely contain our “fresh” pairings), (ii) mean-pool drift in wider representation spaces, (iii) genuine non-monotonicity — to be adjudicated by E17b (anti-leakage construction + last-token control) before any rescue of P-B3.

5.4 Centering as re-manifolding (A4)

172-space atlas: raw cosine separates intra/inter by 0.051 (H-A1 fail, anisotropy floor confirmed); after global centering, inter-space mean collapses to 0.0056 and separation reaches 0.677 — a 13-fold gain; strongest coherent spaces are seasonal and noir-film scenes (C35 and atlas-v2 dual-track report). Cross-space angles concentrate near orthogonality (83–90°): manifold patches are quasi-orthogonal, which is the geometric content of “cross-domain is hard”.

5.5 Metaphor as long geodesic (C30)

If “A is B” activates bidirectionally, A and B inhabit one space at large distance: metaphor difficulty = path length, cross-space mapping is a myth of appearance. Audit experiment (E20: co-activation of 15 canonical pairs over the atlas) is queued.

6 Predictions (each falsifiable, each with a number)

P-B1 (residual bound): for any two specialists, mixture arms must retain >25% off-plane fraction; failure falsifies A3’s constitutive residual. *Status: first confirmation from parameter coupling as well — exp18’s merged $\frac{1}{2}(\Delta W_{spring} + \Delta W_{summer})$ deviates off the behavioral chord on 26/40 probes ($d \geq 0.15$, median 0.212), and the child dominates both parents in held-out NLL.* P-B2 (orthogonal patches): centered inter-space angles concentrate in $[75^\circ, 100^\circ]$; significant mass below would indicate unmapped shared spaces. P-B3 (density-scale curve): mean fresh-probe rank improves monotonically with parameters on a log scale. *Status: breached at 7B (31.0 vs 3B’s 15.5); under E17b audit — stands falsified unless leakage or pooling artifacts are demonstrated.* P-B8 (functorial transfer): chained metaphors A2192B2192C vs direct A2192C at equal token budget; accuracy decay $\ll 1$ under functoriality, ≈ 0.5 under lookup-table transfer (probe epistemics licensed by Yoneda; see companion note).

P-B4 (metaphor distance): pairs rated “hard” by humans show longer atlas shortest paths than “easy” pairs, measured by probe-cascade hops.

P-B9 (the Gram-Schmidt duel): to compare two agents, compare dimension by dimension, projecting out every dimension already contested; the first orthogonal residual decides. Prediction: cross-scale verdicts (0.5B vs 3B on shared probes) are determined by the *presence or absence of a single divergence dimension*, not by whole-spectrum difference — re-reading the C35 ladder (33.4 → 25.9 → 15.5) dimension-wise should localize one axis per step. The last dimension carries

no position effect: orthogonal decomposition is invariant to basis order, so only same-dimension comparisons are admissible (a falsifiable reading of “structure is intelligence”).

P-B10 (ablation, the reverse arm): four sentences from the garden — *add structure, gain function; lose structure, lose function*. The forward arm is on record (C31/C35: adapters install measurable spaces). The reverse arm is the LLM analogue of a gene knockout: project a trained adapter’s centered subspace out of the residual stream at inference ($\Delta W \leftarrow \Delta W - P \Delta W P^\top$); prediction: probes to that space collapse *selectively* (phenotype-specific loss, others within noise), and the ablated model re-learns the space faster than naive base after re-training (the scar retains latent homology). Failure — collapse of everything, or nothing — falsifies the coupling reading of A3/A4.

7 Related positions

Gärdenfors’ *Conceptual Spaces* [1] opened with the complaint that “concept learning is closely tied to the notion of similarity, which has turned out to be problematic for the symbolic and associationistic approaches” (p.10), and proposed a third, geometrical representational level between them — but left it without measuring instruments. This paper derives that missing middle level *independently* — our route ran from face-cell tuning coordinates (Chang & Tsao, Cell 2017) and a JPEG-like intuition (memory stores coefficients, not instances), not from the book itself — quality spaces become centered low-rank subspaces, similarity becomes subspace angles, categorization becomes probe collapse, and the subconceptual/conceptual/symbolic stratification (his Ch.2, p.52) reappears as weights/adapter-space/token-behavior. Earlier ancestors of the same lineage: Tolman’s cognitive map and the grid-cell lineage (neural instantiation of A4); Piaget’s sensorimotor schemes (A2’s developmental cousin); Minsky’s “ability to solve hard problems in constrained environments” (an early rank-raising attempt); manifold hypothesis (Bengio et al.) read here not as a learning assumption but as an ontology of agency; Ebbinghaus’s single-curve memory — refuted by the same rank argument we apply to intelligence verdicts (C23–C25).

8 Limitations

Models 0.5B–7B only (2.4T-class claims unverified, excluded); corpora are small and bilingual (zh-dominant probes); rank spectra depend on the LoRA parameterization (r=16 budget); “agent” here carries no phenomenal commitment — this is a geometry of behavior, not a theory of mind; and the ledger’s own law binds us: every number above was frozen before its judgment.

9 Conclusion

Four sentences — interact-and-change, the curve-atom, composition-plus-residual, the manifold — replace an unanswerable binary with measurable spectra. The garden’s data already speak them: 44° of newness in every mixture, 7° of annotation in every story, 13-fold sight after centering, and a rank ladder climbing with scale. Intelligence, demoted from definition and promoted to dimension.

Reproducibility

All experiments: stateless Kaggle kernels (sha-pinned models), PREREG-gated splits, git-ledger timestamps (LETHE/cora-atlas/chora). The kernel *is* the Dolores control: no session, no memory, no mercy.

Appendix — the ledger of every number cited

Ledger	Quantity	Value
C27/C34	mixture bulge; off-geodesic detour	angle-sum $85^\circ \rightarrow 123^\circ$; 44.0° spring / 46.5° noir (SSS, conserved $\pm 2.5^\circ$)
C28	narrative order vs domain	7.0° vs 85.3° ; ΔNLL flip $+0.031 / -0.016$
C29	permutation order	$56\text{--}60^\circ$; diagonal 9/9; dir-index $+0.42 / -0.21 / \approx 0$
C35	fresh-probe ladder (of 172; chance 86)	$33.4 \rightarrow 25.9 \rightarrow 15.5$, then 31.0 (breach)
atlas-v2	intra/inter separation	raw 0.051; centered 0.677 (inter 0.0056, 13-fold)
